Examples

## Motivations from experimental spectroscopy:

- Vibrational spectroscopy is sensitive probe of structure and dynamics of materials.
- All experimental methods (IR, raman, INS, IXS) provide *incomplete* information.
  - ◆ IR and raman have inactive modes
  - ◆ Hard to distinguish fundamental and overtone (multi-phonon) processes in spectra
  - ◆ No experimental technique provides complete eigenvector information  $\Rightarrow$  mode assignment based on similar materials, chemical intuition, guesswork.
- Hard to find accurate model potentials to describe many systems
- Fitted force-constant models only feasible for small, high symmetry systems.

Examples

## Motivations from predictive modelling

- Lattice dynamics calculation can establish stability or otherwise of putative structure.
- LD gives direct information on interatomic forces.
- LD can be used to study phase transitions via soft modes.
- Quasi-harmonic lattice dynamics can include temperature and calculate ZPE and Free energy of wide range of systems.
- Electron - phonon coupling is origin of (BCS) superconductivity.

Examples

Born-Von  
Karman  
boundary  
conditions

If only nearest neighbours interact:

$$E^{harm} = \frac{1}{2} J \sum_n (u_n - u_{n+1})^2$$

where  $J = \Phi_{nn'}$   
force constant

Equation of motion of n-th atom:

$$M \frac{\partial^2 u_n}{\partial t^2} = - \frac{\partial E^{harm}}{\partial u_n} = -J(2u_n - u_{n+1} - u_{n-1})$$

Examples

Solution is known to be the equation of a travelling wave

$$u_n(t) = \sum_k \tilde{u}_k \exp[i(kx - \omega_k t)] \quad \forall k \in \text{BZ}$$

When this expression is inserted in the equation of motion one obtains:

$$M\omega_k^2 = 2J[1 - \cos(ka)]$$

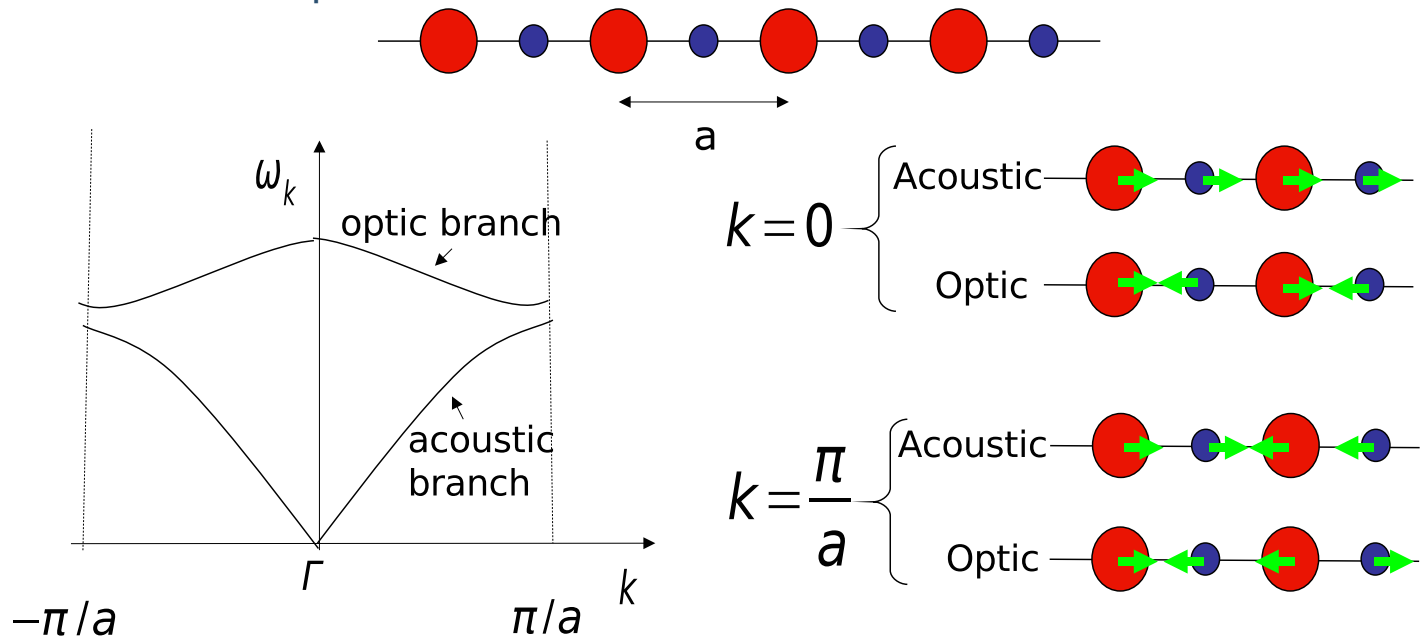

which leads to the following dispersion curve:

$$\omega_k = \sqrt{\frac{4J}{M}} |\sin(ka/2)|$$
$$\forall k \in \text{BZ}$$

More than one atom per unit cell gives rise to *optic modes* with different characteristic dispersion.

Examples

- Vibrational modes in solids take form of *waves* with wavevector-dependent frequencies (just like electronic energy levels).
- $\omega(\mathbf{q})$  relations known as *dispersion curves*
- $N$  atoms in prim. cell  $\Rightarrow 3N$  branches.
- 3 *acoustic* branches corresponding to sound propagation as  $\mathbf{q} \rightarrow 0$  and  $3N - 3$  *optic* branches.

Formal Theory of Lattice Dynamics II

*ab-initio* Lattice Dynamics

Lattice Dynamics in CASTEP

Examples

- Based on expansion of total energy about structural equilibrium co-ordinates

$$E = E_0 + \sum_{\kappa, \alpha} \frac{\partial E}{\partial \mathbf{u}_{\kappa, \alpha}} \cdot \mathbf{u}_{\kappa, \alpha} + \frac{1}{2} \sum_{\kappa, \alpha, \kappa', \alpha'} \mathbf{u}_{\kappa, \alpha} \cdot \Phi_{\alpha, \alpha'}^{\kappa, \kappa'} \cdot \mathbf{u}_{\kappa', \alpha'} + \dots$$

where  $\mathbf{u}_{\kappa, \alpha}$  is the vector of atomic displacements from equilibrium and  $\Phi_{\alpha, \alpha'}^{\kappa, \kappa'}(a)$  is the matrix of *force constants*  $\Phi_{\alpha, \alpha'}^{\kappa, \kappa'}(a) = \frac{\partial^2 E}{\partial \mathbf{u}_{\kappa, \alpha} \partial \mathbf{u}_{\kappa', \alpha'}}$

- At equilibrium the forces  $-\frac{\partial E}{\partial \mathbf{u}_{\kappa, \alpha}}$  are all zero so 1<sup>st</sup> term vanishes.
- In the *Harmonic Approximation* the 3<sup>rd</sup> and higher order terms are assumed to be negligible
- Assume *Born von Karman* periodic boundary conditions and substituting *plane-wave*  $\mathbf{u}_{\kappa, \alpha} = \boldsymbol{\epsilon}_{m\kappa, \alpha \mathbf{q}} \exp(i\mathbf{q} \cdot \mathbf{R}_{\kappa, \alpha} - \omega t)$  yields eigenvalue equation:

$$D_{\alpha, \alpha'}^{\kappa, \kappa'}(\mathbf{q}) \boldsymbol{\epsilon}_{m\kappa, \alpha \mathbf{q}} = \omega_{m, \mathbf{q}}^2 \boldsymbol{\epsilon}_{m\kappa, \alpha \mathbf{q}}$$

where frequencies are square roots of eigenvalues. The **dynamical matrix**

$$D_{\alpha, \alpha'}^{\kappa, \kappa'}(\mathbf{q}) = \frac{1}{\sqrt{M_{\kappa} M_{\kappa'}}} C_{\alpha, \alpha'}^{\kappa, \kappa'}(\mathbf{q}) = \frac{1}{\sqrt{M_{\kappa} M_{\kappa'}}} \sum_a \Phi_{\alpha, \alpha'}^{\kappa, \kappa'}(a) e^{-i\mathbf{q} \cdot \mathbf{R}_a}$$

is the Fourier transform of the force constant matrix.

Examples

- The classical energy expression can be transformed into a quantum-mechanical Hamiltonian for nuclei.
- In harmonic approximation nuclear wavefunction is *separable* into product by mode transformation.
- Each *mode* satisfies harmonic oscillator Schroedinger eqn with energy levels  $E_{m,n} = (n + \frac{1}{2}) \hbar\omega_m$  for mode  $m$ .
- Quantum excitations of modes known as *phonons* in crystal
- Transitions between levels  $n_1$  and  $n_2$  interact with photons of energy  $(n_2 - n_1) \hbar\omega_m$ , ie multiples of *fundamental* frequency  $\omega_m$ .
- In *anharmonic* case where 3<sup>rd</sup>-order term not negligible, *overtone* frequencies are not multiples of fundamental.

Examples

- The dynamical matrix is a  $3N \times 3N$  matrix at each wavevector  $\mathbf{q}$ .
- $D_{\alpha, \alpha'}^{\kappa, \kappa'}(\mathbf{q})$  is a hermitian matrix  $\Rightarrow$  eigenvalues  $\omega_{m, \mathbf{q}}^2$  are real.
- $3N$  eigenvalues  $\Rightarrow$  modes at each  $\mathbf{q}$  leading to  $3N$  branches in dispersion curve.
- The mode eigenvector  $\epsilon_{m\kappa, \alpha}$  gives the atomic displacements, and its symmetry can be characterised by group theory.
- Given a force constant matrix  $\Phi_{\alpha, \alpha'}^{\kappa, \kappa'}(a)$  we have a procedure for obtaining mode frequencies and eigenvectors over entire BZ.
- In 1970s force constants fitted to experiment using simple models.
- 1980s - force constants calculated from empirical potential interaction models (now available in codes such as GULP)
- mid-1990s - development of *ab-initio* electronic structure methods made possible calculation of force constants with no arbitrary parameters.

## The frozen phonon method:

- Create a structure perturbed by guessed eigenvector
- evaluate *ground-state energy* as function of *amplitude*  $\lambda$  with series of single-point energy calculations on perturbed configurations.
- Use  $E_0(\lambda)$  to evaluate  $k = \frac{d^2 E_0}{d\lambda^2}$
- Frequency given by  $\sqrt{k/\mu}$ . ( $\mu$  is reduced mass)
- Need to use supercell commensurate with  $\mathbf{q}$ .
- Need to identify eigenvector in advance (perhaps by symmetry).
- Not a general method: useful only for small, high symmetry systems or limited circumstances otherwise.
- Need to set this up “by hand” customised for each case.

Examples

## The finite displacement method:

- Displace ion  $\kappa'$  in direction  $\alpha'$  by small distance  $\pm u$ .
- Use single point energy calculations and evaluate *forces* on *every* ion in system  $F_{\kappa,\alpha}^+$  and  $F_{\kappa,\alpha}^-$  for +ve and -ve displacements.
- Compute numerical derivative using central-difference formula

$$\frac{dF_{\kappa,\alpha}}{du} \approx \frac{F_{\kappa,\alpha}^+ - F_{\kappa,\alpha}^-}{2u} = \frac{d^2 E_0}{du_{\kappa,\alpha} du_{\kappa',\alpha'}}$$

- Have calculated entire *row*  $k', \alpha'$  of  $D_{\alpha,\alpha'}^{\kappa,\kappa'}(\mathbf{q} = 0)$
- Only need  $6N_{\text{at}}$  SPE calculations to compute entire dynamical matrix.
- This is a *general* method, applicable to any system.
- Can take advantage of space-group symmetry to avoid computing symmetry-equivalent perturbations.
- Like frozen-phonon method, works only at  $\mathbf{q} = 0$ .

Fourier Interpolation of  
dynamical Matrices

Lattice Dynamics in  
CASTEP

Examples

The *supercell method* is an extension of the finite-displacement approach.

- Relies on *short-ranged* nature of FCM;  $\Phi_{\alpha,\alpha'}^{\kappa,\kappa'}(a) \rightarrow 0$  as  $R_a \rightarrow \infty$ .
- For non-polar insulators and most metals  $\Phi_{\alpha,\alpha'}^{\kappa,\kappa'}(a)$  decays as  $1/R^5$  or faster.
- For polar insulators Coulomb term decays as  $1/R^3$
- Can define “cut off” radius  $R_c$  beyond which  $\Phi_{\alpha,\alpha'}^{\kappa,\kappa'}(a)$  can be treated as zero.

■ In supercell with  $L > 2R_c$  then  $C_{\alpha,\alpha'}^{\kappa,\kappa'}(\mathbf{q} = 0) = \Phi_{\alpha,\alpha'}^{\kappa,\kappa'}(a)$ .

■ Method:

1. choose sufficiently large supercell and compute  $C_{\alpha,\alpha'}^{\kappa,\kappa'}(\mathbf{q}_{\text{supercell}} = 0)$  using finite-displacement method.
2. This object is just the real-space force-constant matrix  $\Phi_{\alpha,\alpha'}^{\kappa,\kappa'}(a)$ .
3. Fourier transform using

$$D_{\alpha,\alpha'}^{\kappa,\kappa'}(\mathbf{q}) = \frac{1}{\sqrt{M_{\kappa} M_{\kappa'}}} \sum_a \Phi_{\alpha,\alpha'}^{\kappa,\kappa'}(a) e^{-i\mathbf{q} \cdot \mathbf{R}_a}$$

to obtain dynamical matrix of primitive cell at *any* desired  $\mathbf{q}$ .

4. Diagonalise  $D_{\alpha,\alpha'}^{\kappa,\kappa'}(\mathbf{q})$  to obtain eigenvalues and eigenvectors.

- This method is often (confusingly) called the “direct” method.

Fourier Interpolation of  
dynamical Matrices

Lattice Dynamics in  
CASTEP

Examples

Goal is to calculate the *2nd derivatives* of energy to construct FCM or  $D_{\alpha, \alpha'}^{\kappa, \kappa'}(\mathbf{q})$ .

- Energy  $E = \langle \psi | \hat{H} | \psi \rangle$  with  $\hat{H} = \nabla^2 + V_{\text{SCF}}$
- Force  $F = -\frac{dE}{d\lambda} = -\left\langle \frac{d\psi}{d\lambda} \left| \hat{H} \right| \psi \right\rangle - \langle \psi | \hat{H} \left| \frac{d\psi}{d\lambda} \right\rangle - \langle \psi | \frac{dV}{d\lambda} | \psi \rangle$   
where  $\lambda$  represents an atomic displacement perturbation.
- If  $\langle \psi |$  represents the ground state of  $\hat{H}$  then the first two terms vanish because  $\langle \psi | \hat{H} \left| \frac{d\psi}{d\lambda} \right\rangle = \epsilon_n \langle \psi | \left| \frac{d\psi}{d\lambda} \right\rangle = 0$ . This is the *Hellman-Feynmann Theorem*.
- Force constants are the *second* derivatives of energy  
 $k = \frac{d^2 E}{d\lambda^2} = -\frac{dF}{d\lambda} = \left\langle \frac{d\psi}{d\lambda} \left| \frac{dV}{d\lambda} \right| \psi \right\rangle + \langle \psi | \frac{dV}{d\lambda} \left| \frac{d\psi}{d\lambda} \right\rangle - \langle \psi | \frac{d^2 V}{d\lambda^2} | \psi \rangle$
- None of the above terms vanishes.
- Second derivatives need **linear response** of wavefunctions *wrt* perturbation ( $\left\langle \frac{d\psi}{d\lambda} \left| \right. \right.$ ).
- In general  $n^{\text{th}}$  derivatives of wavefunctions needed to compute  $2n + 1^{\text{th}}$  derivatives of energy. This result is the “*2n + 1 theorem*”

Scary Maths

Fourier Interpolation of  
dynamical Matrices

Lattice Dynamics in  
CASTEP

Examples

- In DFPT need *first-order* KS orbitals  $\phi^{(1)}$ , the *linear response* to  $\lambda$ .
- $\lambda$  may be a displacement of atoms with wavevector  $\mathbf{q}$  (or an electric field  $E$ .)
- If  $\mathbf{q}$  incommensurate  $\phi^{(1)}$  have Bloch-like representation:  
 $\phi_{\mathbf{k},\mathbf{q}}^{(1)}(\mathbf{r}) = e^{-i(\mathbf{k}+\mathbf{q})\cdot\mathbf{r}} u^{(1)}(\mathbf{r})$  where  $u^{(1)}(\mathbf{r})$  has periodicity of unit cell.  
 $\Rightarrow$  can store  $u^{(1)}(\mathbf{r})$  in computer rep'n using basis of *primitive* cell.
- First-order response orbitals are solutions of **Sternheimer equation**

$$\left( H^{(0)} - \epsilon_m^{(0)} \right) \left| \phi_m^{(1)} \right\rangle = -P_c v^{(1)} \left| \phi_m^{(0)} \right\rangle$$

$P_c$  is projection operator onto unoccupied states. First-order potential  $v^{(1)}$  includes response terms of Hartree and XC potentials and therefore depends on first-order *density*  $n^{(1)}(\mathbf{r})$  which depends on  $\phi^{(1)}$ .

Finding  $\phi^{(1)}$  is therefore a *self-consistent* problem just like solving the Kohn-Sham equations for the ground state.

- Two major approaches to finding  $\phi^{(1)}$  are suited to plane-wave basis sets:
  - ◆ Green's function (S. Baroni *et al* (2001), Rev. Mod. Phys **73**, 515-561).
  - ◆ Variational DFPT (X. Gonze (1997) PRB **55** 10377-10354).

CASTEP uses Gonze's variational DFPT method.

- DFPT has huge advantage - can calculate response to *incommensurate*  $\mathbf{q}$  from a calculation on primitive cell.
- Disadvantage of DFPT - lots of programming required.

Fourier Interpolation of  
dynamical Matrices

Lattice Dynamics in  
CASTEP

Examples

- DFPT formalism requires self-consistent iterative solution for every separate  $\mathbf{q}$ .
- Hundreds of  $\mathbf{q}$ 's needed for good dispersion curves, thousands for good Phonon DOS.
- Can take advantage of short-range nature of real-space FCM  $\Phi_{\alpha,\alpha'}^{\kappa,\kappa'}(a)$ .
- Compute  $D_{\alpha,\alpha'}^{\kappa,\kappa'}(\mathbf{q})$  on a Monkhorst-Pack grid of  $\mathbf{q}$  vectors.
- Approximation to FCM in  $p \times q \times r$  supercell given by Fourier transform of dynamical matrices on  $p \times q \times r$  grid.

$$\Phi_{\alpha,\alpha'}^{\kappa,\kappa'}(a) = \sum_{\mathbf{q}} C_{\alpha,\alpha'}^{\kappa,\kappa'}(\mathbf{q}) e^{i\mathbf{q} \cdot \mathbf{R}_a}$$

- Fourier transform using to obtain dynamical matrix of primitive cell at *any* desired  $\mathbf{q}$ , Exactly as with Finite-displacement-supercell method
- Diagonalise mass-weighted  $D_{\alpha,\alpha'}^{\kappa,\kappa'}(\mathbf{q})$  to obtain eigenvalues and eigenvectors.
- Longer-ranged coulombic contribution varies as  $1/R^3$  but can be handled analytically.
- Need only DFPT calculations on a few tens of  $\mathbf{q}$  points on grid to calculate  $D_{\alpha,\alpha'}^{\kappa,\kappa'}(\mathbf{q})$  on arbitrarily dense grid (for DOS) or fine (for dispersion) path.

calculation

Examples

CASTEP can perform *ab-initio* lattice dynamics using

- Primitive cell finite-displacement at  $\mathbf{q} = 0$
- Supercell finite-displacement for any  $\mathbf{q}$
- DFPT at arbitrary  $\mathbf{q}$ .
- DFPT on M-P grid of  $\mathbf{q}$  with Fourier interpolation to arbitrary fine set of  $\mathbf{q}$ .

Full use is made of space-group symmetry to only compute only

- symmetry-independent elements of  $D_{\alpha, \alpha'}^{\kappa, \kappa'}(\mathbf{q})$
- $\mathbf{q}$ -points in the irreducible Brillouin-Zone for interpolation
- electronic  $k$ -points adapted to symmetry of perturbation.

Limitations: DFPT currently implemented only for norm-conserving pseudopotentials and insulators. (Need `fix_occupancy = T`, not just band gap.)

Examples

Lattice dynamics assumes atoms at mechanical equilibrium.

**Golden rule:** *The first step of a lattice dynamics calculation is a high-precision geometry optimisation*

- Parameter `task = phonon` selects lattice dynamics calculation.
- Iterative solver tolerance is `phonon_energy_tol`. Value of  $1e - 5 \text{ ev/ang}^{**2}$  usually sufficient. Sometimes need to increase `phonon_max_cycles`
- Need very accurate *ground-state* as prerequisite for DFPT calculation  
`elec_energy_tol` needs to be roughly *square* of `phonon_energy_tol`
- N.B. Defaults are not very good in CASTEP 4.0. Fixed in 4.1.
- $D_{\alpha, \alpha'}^{\kappa, \kappa'}(\mathbf{q})$  calculated at  $\mathbf{q}$ -points specified in *cell* file by one of
  - ◆ `%BLOCK phonon_kpoint_list` for the explicitly named points
  - ◆ `%BLOCK phonon_kpoint_path` to construct a path joining the nodal points given. Spacing along path is `phonon_kpoint_path_spacing`
  - ◆ `phonon_kpoint_mp_grid p q r` and possibly `phonon_kpoint_mp_offset 0.125 0.125 0.125` to explicitly specify a M-P grid for a DOS.
  - ◆ `phonon_kpoint_mp_spacing  $\delta q$  1/ang` to generate a M-P grid of a specified linear spacing

Running a phonon  
calculation

Examples

To select set `phonon_fine_method = interpolate`

Specify grid of  $q$ -points using `phonon_kpoint_mp_grid p q r`.

**Golden rule of interpolation:** Always include the  $\Gamma$  point (0,0,0) in the interpolation grid. For even  $p, q, r$  use *shifted* grid `phonon_fine_kpoint_mp_offset 0.125 0.125 0.125` to shift one point to  $\Gamma$

$D_{\alpha, \alpha'}^{\kappa, \kappa'}(\mathbf{q})$  interpolated to  $q$ -points specified in *cell* file by one of

- `%BLOCK phonon_fine_kpoint_list` for the explicitly named points
- `%BLOCK phonon_fine_kpoint_path` to construct a path joining the nodal points given. Spacing along path is `phonon_fine_kpoint_path_spacing`
- `phonon_fine_kpoint_mp_grid p q r` and possibly `phonon_fine_kpoint_mp_offset 0.125 0.125 0.125` to explicitly specify a M-P grid for a DOS.
- `phonon_fine_kpoint_mp_spacing  $\delta q$  1/ang` to generate a M-P grid of a specified linear spacing

Real-space force-constant matrix is stored in `.check` file. All `fine_kpoint` parameters can be changed on a continuation run. Interpolation is very fast.  $\Rightarrow$  can calculate fine dispersion plot and DOS on a grid rapidly from one DFPT calculation.

Parameter `phonon_force_constant_cutoff` applies real-space cutoff to  $\Phi_{\alpha, \alpha'}^{\kappa, \kappa'}(a)$ . Default is chosen according to MP grid.

CASTEP phonon  
calculations III -  
Supercell

Running a phonon  
calculation

Examples

- To select set `phonon_fine_method = supercell`

```
%BLOCK phonon_supercell_matrix
2 0 0
0 2 0
0 0 2
%ENDBLOCK phonon_supercell_matrix
```
- Set supercell in `.cell` file, eg  $2 \times 2 \times 2$  using

```
%BLOCK phonon_supercell_matrix
2 0 0
0 2 0
0 0 2
%ENDBLOCK phonon_supercell_matrix
```
- $D_{\alpha, \alpha'}^{\kappa, \kappa'}(\mathbf{q})$  interpolated to  $\mathbf{q}$ -points specified in `cell` file by one of same `phonon_fine_kpoint` keywords as for interpolation.
- Kpoints for supercell set using block or grid keywords `supercell_kpoint...`
- `phonon_force_constant_cutoff` applies as for Interpolation calculation.
- Real-space force-constant matrix is stored in `.check` file.
- As with interpolation, all `fine_kpoint` parameters can be changed on a continuation run. Interpolation is very fast.  $\Rightarrow$  can calculate fine dispersion plot and DOS on a grid rapidly from one DFPT calculation.

```
%BLOCK phonon_supercell_matrix
1 1 -1
1 -1 1
-1 1 1
%ENDBLOCK phonon_supercell_matrix
```
- Tip. For *fcc* primitive cells use non-diagonal matrix to make cubic supercell.
- Convergence: Need very accurate forces to take their derivative.
- Need good representation of any pseudo-core charge density and augmentation charge for ultrasoft potentials on fine FFT grid. Usually need larger `fine_gmax` (or `fine_grid_scale`) than for geom opt/MD to get good results.

Running a phonon  
calculation

Examples

- Phonon calculations can be lengthy. CASTEP saves partial calculation periodically in `.check` file if keywords `num_backup_iter  $n$`  or `backup_interval  $t$` . Backup is every  $n$  q-vectors or every  $t$  seconds.
- Phonon calculations have high inherent parallelism. Because perturbation breaks symmetry relatively large electronic  $k$ -point sets are used.
- Number of  $k$ -points varies depending on symmetry of perturbation.
- Try to choose number of processors to make best use of  $k$ -point parallelism. If  $N_k$  not known in advance choose  $N_P$  to have as many different prime factors as possible - **not just 2!**

- Previous *ab-initio* calculations on isolated  $\text{ReH}_9^{2+}$  ion gave poor fit to INS.
- Repeat isolated ion using CASTEP.
- CASTEP model: periodic array of ions in charged cell. Exp  $1/V$  scaling and take  $V \rightarrow \infty$  limit.
- $V \rightarrow \infty$  frequencies in agreement with isolated ion calcs.
- $\Rightarrow$  large ( $\approx 150 \text{ cm}^{-1}$ ) crystal field shift
- Can also extrapolate *down* to  $V_{\text{xtal}}$ .
- Extrapolated ion freqs are very close to A-point crystal freqs.
- Crystal field shift is almost entirely a periodic volume effect.
- Anion modes completely insensitive to presence of cation!

*ab-initio* lattice dynamics calculations are very sensitive to convergence issues. A good calculation must be well converged as a function of

1. plane-wave cutoff
  2. electronic kpoint sampling of the Brillouin-Zone (for crystals)  
(under-convergence gives poor acoustic mode dispersion as  $q \rightarrow 0$ )
  3. geometry. Co-ordinates must be well converged with forces close to zero  
(otherwise calculation will return *imaginary* frequencies.)
  4. For DFPT calculations need high degree of SCF convergence of ground-state wavefunctions.
  5. supercell size for “molecule in box” calculation and slab thickness for surface/slab calculation.
  6. Fine FFT grid for finite-displacement calculations.
- Accuracies of  $25\text{-}50\text{ cm}^{-1}$  usually achieved or bettered with DFT.
  - need GGA functional e.g. PBE, PW91 for hydrogenous and H-bonded systems.
  - When comparing with experiment remember that disagreement may be due to *anharmonicity*.
  - Less obviously *agreement* may also be due to anharmonicity. There is a “lucky” cancellation of anharmonic shift by PBE GGA error in OH stretch modes!

Convergence issues for  
lattice dynamics

“Scaling” and other  
cheats

- DFT usually gives frequencies within a few percent of experiment. Exceptions are usually strongly-correlated systems, e.g. some transition-metal Oxides where DFT description of bonding is poor.
- Discrepancies can also be due to anharmonicity. A frozen-phonon calculation can test this.
- In case of OH-bonds, DFT errors and anharmonic shift cancel each other!
- In solid frequencies may be strongly pressure-dependent. DFT error can resemble *effective pressure*. In that case, best comparison with expt. may not be at experimental pressure.
- Hartree-Fock approximation *systematically* overestimates vibrational frequencies by 5-15%. Common practice is to multiply by “scaling factor”  $\approx 0.9$ .
- Scaling not recommended for DFT where error is not systematic. Over- and under-estimation equally common.
- For purposes of mode assignment, or modelling experimental spectra to compare intensity it can sometimes be useful to apply a small empirical shift on a per-peak basis. This does not generate an “*ab-initio* frequency”.
